Acceptance and Invitation Letter

2016 International Conference on Advanced Materials Science and Environmental Engineering (AMSEE2016)
http://www.amsee2016.org/

June 26-27, 2016, Chiang Mai, Thailand

Paper ID:
Paper title: Microwave Drying Machine for Sea Bass Leathers
Authors: Tantiviwat Sugchai, Sudram Arkom, Chanthong Apirun and Kerdtongmee Priwan

Dear Authors,

Thank you for submitting the above paper to the 2016 International Conference on Advanced Materials Science and Environmental Engineering (AMSEE2016). AMSEE2016 will be published by Atlantis Press on Advances in Engineering Research (ISSN 2352-5401) and will be online available in full text via the press platform. All accepted papers will be submitted for indexing by ISI, CPC1-S (ISTP indexing) and EI Compendex. Excellent papers will be selected and published on SCI and EI journals.

As a result of the reviews and revisions, we are pleased to inform you that the paper above has been formally accepted for publication on the above AMSEE2016 conference proceedings. We appreciate if you could send the final version of the manuscript at your earliest convenience, to ensure a timely publication of the paper. When submitting the final version, please highlight any changes or amendments made to the manuscript.

Thank you for your contribution to the AMSEE2016 and we are looking forward to your future participation on June 26-27, 2016, Chiang Mai, Thailand.

Welcome to AMSEE2016. Welcome to Chiang Mai, Thailand.

Yours sincerely,

AMSEE2016 Organizing Committee

March 25, 2016
Microwave Drying Machine for Sea Bass Leathers

Abstract—Microwave drying is a dehydration process that is often used to preserve a food or material. In this study, sea bass leathers were dried by microwave technique. In order to improve the productivity, the microwave energy was applied to decrease the drying time. The sea bass leathers were dried to the desired final moisture content, whereby 70-80 °C hot air for baking are generated by the heating process from magnets and three levels, power microwave consists of approximately 60 °C, 50 °C, 30 °C and drying time are 15-30 minutes based on power ON per unit of total magnetron respectively. The relation between the final parameter of microwave power, number of magnetron and the temperature is presented as well. This method can be applied in dehydration with microwave techniques.

Keywords: Microwave drying; Dehydration; Rate of drying; Sea bass leathers.

I. INTRODUCTION

Microwaves refer to the electromagnetic waves in the frequency range of 300 MHz up to 300 GHz. Since the great experiments were carried out by Dr. Percy Spencer in 1946, microwave heating has been used widely in the food industry [1]. Once the microwave energy is absorbed, polar molecules and ions inside the food will rotate or collide according to the alternating electromagnetic field and heat is subsequently generated from cooking. Nevertheless, and in agreement with the industrial, only 915 MHz and 2.45 GHz are used for food applications, especially the second due to its worldwide availability. The dissipation of this energy has been reported by other authors indicating some example of this process is solar drying [2], vacuum drying [3], freeze drying [4], microwave drying [5], microwave vacuum drying [6], microwave freeze drying [7], infrared radiation drying [8], etc.

In general, technology of microwave for food in Thailand domestic is widely used only in household cooking. Nowadays, for the use of microwave technology in the industry. There is no widespread usage. Because of the lack of understanding in the application of microwave heating. In addition, entrepreneurs think that microwave on high technology are complicate and may cause more harm than the investigations in the baking process, rather than using another method. In Songkhla, Thailand is the source of the most delicious Sea basses because the surrounding white Seabass. The Ko Yo Island area contains both salt water and fresh water, brackish water changes according to the each season of the year. It is the source of the famous sea bass. When the frozen industrial came to carve sea bass and fish most exported to Japan. There is still leather by the remaining fish. The idea of entrepreneurs (T.I.P.) were converted fish leather to food. The importance of the remaining sea bass leather has dried and fried tried a local distributor. As well as the widely popular both at country and abroad. Usually baked seashells skins, it will consist of 2 ways: baking with solar drying and hot air, but the two methods, it will use for a long period of time to bake. By baking with hot air. Frying fish leather successfully will take about 40-50 minutes.

Therefore, this research presents ideas to design with baking using microwave [9-11], which can reduce production time, and consider the value of food, such as the crunchy and still the same softness as well as storage for long periods as with the traditional hot air drying. There is also a concept that combination of heat from microwave and the hot-air for baking are generated by the heating process from magnets.

II. RELATED OF MICROWAVE HEATING THEORIES

The basic equation in microwave heating is a model of transverse electromagnetic (TEM) mode. The microwave with x- and y-components of the electromagnetic fields and they are assumed to propagate at frequency 915 MHz or 2450 MHz along the z-component direction. Maxwell's equations in vacuum microwave heating, the electromagnetic wave collaboration with materials [12-13] is expressed in four equations:

\[
\begin{align*}
\nabla \cdot \mathbf{E} &= \frac{\partial \mathbf{B}}{\partial t} = \sigma (\nabla \times \mathbf{H}) \cdot \mathbf{N} \\
\n\nabla \cdot \mathbf{H} &= -\frac{\partial \mathbf{D}}{\partial t} = \sigma (\nabla \times \mathbf{E}) \cdot \mathbf{N} \\
\n\nabla \times \mathbf{E} &= 0, \quad \nabla \times \mathbf{H} = 0
\end{align*}
\]

\[
\begin{align*}
\n\frac{\partial \mathbf{E}}{\partial t} &= (\epsilon - j\omega \mu) \mathbf{E} \\
\n\frac{\partial \mathbf{B}}{\partial t} &= (\epsilon - j\omega \mu) \mathbf{B}
\end{align*}
\]

where \( \mathbf{E} \) is the electric field intensity (V/m), \( \mathbf{H} \) is the magnetic field intensity (A/m), \( \sigma \) is the magnetic flux density (Wb/m²), \( D \) is the electric flux density (C/m²), \( \mu \) is the magnetic permeability, \( \epsilon \) is the electric permittivity, \( \omega \) is the angular frequency, \( t \) is the time, and \( \mathbf{N} \) is the normal vector.

\( \mathbf{N} \) is the normal vector, \( \epsilon \) is the electric permittivity, \( \mu \) is the magnetic permeability, \( \omega \) is the angular frequency, and \( t \) is the time.
Waveguide is a structure that guides waves for electromagnetic waves, it allows a signal to propagate with minimal loss of energy by restricting expansion. In microwave oven, the waveguide transfers power from the magnetron, where waves are formed in the following food. Electromagnetic waveguides are evaluated by evaluating Maxwell's equations or their reduced form the electromagnetic wave equation with boundary conditions are determined by the properties of the materials. From Maxwell's equations leading to curl equation is given by

$$\nabla \times E = -j \omega \mu H \quad \nabla \times H = j \omega \varepsilon E$$  \hspace{1cm} (3)

The relationship of $E$ and $H$ in the direction of movement in the z-axis, where $E_z, H_z \propto e^{j\omega t}$ ($t = x, y, z$) can be expressed as

$$\frac{\partial E_z}{\partial y} - \frac{\partial H_z}{\partial x} = -j \omega H_z$$
$$\frac{\partial H_z}{\partial x} - \frac{\partial E_z}{\partial y} = j \omega E_z$$  \hspace{1cm} (4)

$$\frac{\partial E_z}{\partial y} - \frac{\partial H_z}{\partial x} = -j \omega H_z$$
$$\frac{\partial H_z}{\partial x} - \frac{\partial E_z}{\partial y} = j \omega E_z$$

where $h^2 = \varepsilon_0 \mu_0 \mu_s \mu_t$, written in the form of a relationship element in the transverse is as follows:

$$E_z = \frac{1}{h^2} \left( \frac{\partial E_z}{\partial y} - j \frac{\partial H_z}{\partial x} \right), \quad E_z = -\frac{1}{h^2} \left( \frac{\partial E_z}{\partial y} + j \frac{\partial H_z}{\partial x} \right)$$

$$H_z = \frac{1}{h^2} \left( -j \frac{\partial E_z}{\partial y} + \frac{\partial H_z}{\partial x} \right), \quad H_z = -\frac{1}{h^2} \left( j \frac{\partial E_z}{\partial y} - \frac{\partial H_z}{\partial x} \right)$$  \hspace{1cm} (5)

TEM mode, electromagnetic wave is $E_z = H_z = 0$. TE mode is $E_z = 0$ and TM mode is $H_z = 0$ respectively. The Microwave heating is used in the form of the signal transmission cable, the metallic wave that has a rectangular shape with dimensions width by length $b \times a$ is given by

$X_{TM} = 0, \quad H_{TM} = 0 \quad$ and $\quad E_z = X(\varphi) Y(z) e^{j\omega t}$  \hspace{1cm} (6)

$$\frac{d^2}{dx^2} X + \frac{1}{k_z^2} X = 0, \quad \frac{d^2}{dz^2} Y + k_z^2 Y = 0$$

$X''(z) Y''(z) e^{j\omega t} = X(z) Y(z) e^{j\omega t}$  \hspace{1cm} (7)

$$d^2X + k_z^2 X = 0, \quad d^2Y + k_z^2 Y = 0$$

The general equation is in the form of a sine function.

$X(\varphi) = A \cos(\varphi), \quad Y(z) = B \sin(\varphi)$

$X(\varphi) = C \cos(\varphi), \quad Y(z) = D \sin(\varphi)$

The electric field at the edge of the waveguide, leading the waves to the position $x = 0$ and $y = 0$

$$E_z(x = 0) = \{A \cos(0) \sin(0) = \sum k \sin(k_y) \sin(k_x) \} e^{j\omega t} = 0$$
$$E_z(y = 0) = \{A \cos(0) \sin(0) = \sum k \sin(k_y) \sin(k_x) \} e^{j\omega t} = 0$$  \hspace{1cm} (10)

For TM mode, consider the relationship of the edge of the waveguide, leading the waves to the position $x = a$ and $y = b$

$$E_z(x = a) = \sum k \sin(k_y) \sin(k_x) e^{j\omega t}$$
$$E_z(y = b) = \sum k \sin(k_y) \sin(k_x) e^{j\omega t}$$  \hspace{1cm} (11)

Substituting $k_n = \frac{mn}{a}, \quad k_b = \frac{mn}{b}$ where $m, n$ are 1, 2, 3, 4, ..., $f(c_{TM})$ is cut off frequency with $m, n$ mode whereby all relations leading to the equation are as follows:

$$E_z = E_0 \sin \left( \frac{mn}{a} \right) \sin \left( \frac{mn}{b} \right) e^{j\omega t}$$

$$k^2 = \left( \frac{mn}{a} \right)^2 \sin^2 \left( \frac{mn}{a} \right) + \left( \frac{mn}{b} \right)^2 \sin^2 \left( \frac{mn}{b} \right)$$

$$\gamma_m = \alpha + j \beta = \sqrt{\left( \frac{mn}{a} \right)^2 \sin^2 \left( \frac{mn}{a} \right) + \left( \frac{mn}{b} \right)^2 \sin^2 \left( \frac{mn}{b} \right) - \sigma^2 \mu_t}$$

$$\tau_m = \frac{1}{2} \sqrt{\left( \frac{mn}{a} \right)^2 \sin^2 \left( \frac{mn}{a} \right) + \left( \frac{mn}{b} \right)^2 \sin^2 \left( \frac{mn}{b} \right)}$$  \hspace{1cm} (12)

For TE mode, equation is as follows:

$$H_z = H_0 \cos \left( \frac{mn}{a} \right) \cos \left( \frac{mn}{b} \right) e^{j\omega t}$$

$$f(c_{TM}) = \sqrt{\left( \frac{mn}{a} \right)^2 \sin^2 \left( \frac{mn}{a} \right) + \left( \frac{mn}{b} \right)^2 \sin^2 \left( \frac{mn}{b} \right) + \frac{n^2}{a^2} \sin^2 \left( \frac{mn}{a} \right) + \frac{n^2}{b^2} \sin^2 \left( \frac{mn}{b} \right)}$$

$$\gamma_m = \frac{1}{2} \sqrt{\left( \frac{mn}{a} \right)^2 \sin^2 \left( \frac{mn}{a} \right) + \left( \frac{mn}{b} \right)^2 \sin^2 \left( \frac{mn}{b} \right)}$$  \hspace{1cm} (13)

Sea bass feathers are low-loss materials; they absorb microwave power and leads to temperature increase. The temperature variation is governed by heat transfer equation [10], [14] which describes the space and time behavior of the temperature field is given by

$$\rho C_v \frac{\partial T}{\partial t} - \nabla \cdot (k \nabla T) = P_c$$

$$\rho C_v \frac{\partial T}{\partial t} - \kappa \nabla^2 T = P_c$$

$$\rho C_v \frac{\partial T}{\partial t} - \kappa \nabla^2 T = \frac{1}{C_0} \sigma (\sigma + 1) \left( T - T_0 \right)$$

where $C_v$ and $k$ as thermal conductivity and specific heat capacity respectively. $T$ is the temperature. $P_c$ is the initial heat of the material and $\kappa$ is the effective dielectric conductivity. $t$ is the penetrability of free surface and $\sigma$ is the imaginary part of the penetrability of the material.

The radiation capacity [15] is described as water gain as follow:

$$= \text{Water gain} = \frac{W_c - W}{W}$$

where $W_c$ is weight after rehydration at time $t$ and $W$ is weight before rehydration at time $t$ respectively.
The Lewis model has been widely applied to predict the thin-layer drying data of food products exhibiting a decreasing drying rate [16], which only takes into account the surface resistance to moisture transfer. The moisture ratio (MR) was calculated using the following equation:

$$MR = \frac{M_t - M_e}{M_0 - M_e}$$  \hspace{1cm} (16)

where $M_t$ is the experimental moisture content, $M_e$ is the equilibrium moisture content and $M_0$ is the initial moisture content respectively.

For constant microwave power, decrease in drying rate was same primarily for all pulse ratios [17]. The PR was calculated using the following equation:

$$PR = \frac{t_{on} - t_{off}}{t_{on}}$$  \hspace{1cm} (17)

where $t_{on}$ is magnetron power ON time and $t_{off}$ magnetron power OFF time. For example, when ON time was 30 s / 30 s (PR = 2.0), 20 s / 40 s (PR = 3.0), and 10 s / 50 s (PR = 6.0).

III. PROTOTYPE OF MICROWAVE DRYING MACHINE

The dimension of rectangular waveguide is important because waveguides are used to transfer electromagnetic power efficiently; has been applied to the construction of heating. Based on theoretical in topic II consideration of prototype of microwave drying machine, the size of this waveguide (b, a) are 11.6 cm respectively. From the simulation with Matlab to find out the cutoff frequency by considering cases of basic mode $m=1$, $n=0$. The cutoff frequency is 1.36 GHz, for cutoff frequency design must less than fundamental frequency $f_c < f_0$ where $f_0 = 2.45$ GHz. The machine was presented in fully parameterized model for microwave drying. All geometrical is shown in Fig. I. This microwave machine consists of many drying cells (a cell in cavity), each of them is based on the idea of open resonator. Each of cell in cavity has own magnetron located in waveguide oven. In addition, the steam can also rotate the containers so that heating it across all sectors. All the element of a machine is as shown geometric shapes machine 3D schematics in Fig. II.
IV. RESULTS AND DISCUSSION

Preliminary testing machine, the results of moisture in the sea bass leather, found that the moisture content of 20 pieces before baking (measuring 1 piece at a time), there will be moisture equals 3.63 - 4.75% moisture after baking and it will have a value of 70% sea bass leather moisture (determination moisture per 1 piece). The moisture equals 2.50 - 3.80%. From the results it can be seen that the baking of sea bass leather moisture is slightly changed. The results are preliminary information for consideration in baking by microwave drying. However, the problem that is occurring, we can see that the baking material is moist and the process can reduce rate of moisture. This research will have to take into consideration the cost-effectiveness and cost for energy consumption and time needed, as well as the quantity that can be baked in each time. In fact, regardless of the sea bass leathers are not burn or scorch distortion after baking. As well as the taste must remain the same as the original, traditional. From the tested machines can summarize in the Table 1. The measured results of microwave drying machine for sea bass leather in Table 1 are in good agreement with the measured results of the traditional process but can reduce the time to be a better than in the past of drying.

V. CONCLUSIONS

The results of microwave drying machine for sea bass leathers revealed the following conclusion, increasing drying temperature with microwave power of magnetron can reduce the drying time of sea bass leathers but sea bass leathers are not burn or scorch distortion after baking. Among the drying parameters are studied, range of temperature are 40 - 80 °C and 60%, 50% and 30% microwave power of magnetron could be mentioned for drying are in good agreement with the measured results of the traditional process but can reduce the time to be a better than in the past methods of drying.
